# Blood Pressure Distribution in an Iranian Adolescent Population: "Tehran Lipid and Glucose Study" 

A Ghanbarian, MD, N Rezaei-Ghaleh, MD, P Salehi, MD, F Azizi, MD<br>1. I:ndocrine Research Center, Shaheed Beheshti University of Medical Sciences, Tehran, Iran

#### Abstract

Summary Significant hypertension in adolescence is defined according to Blood Pressure (BP) distribution among general population. The present study was conducted to determine the BP distribution in Iranian adolescents. In a population based study held in Tehran, BP data for 2560 participants aged 10.17 years ( 1247 boys and 1313 gills) were collected. The 90th and 95 th percentiles of systolic (SBP) and diastolic BP (DBP) were obtained for different age and height subgatops of boys and gifls. While the 90 th and 95 th percentiles of SBP obtained in our study were generally lower than intemational guidelines, the corresponding percentiles of DBP were higher. Significant associations were found between BP and age, height, weight and BMI. According to out findings, it is necessary to prepare BP reference tables according to regional surveys.

Key Words: Adolescence, Blood pressure, Epidemiology, TLGS

## Introduction

High blood pressure is one of the most important risk factors for cardiovascular diseases ${ }^{1.4}$. This modifiable risk factor is a common health problem in Iran ${ }^{5}$. Some scientists believe that the roots of essential hypertension in adults are already present in childhood and adolescence ${ }^{6-9}$. According to the National Institute of Health (NIH), blood pressure values in childhood can predict values of blood pressure 15 years later. Longitudinal observations have shown that blood pressure increases consistently from infancy to adolescence and then adulthood ${ }^{10-11}$. In addition to age, the other important determinant of blood pressure in childhood and adolescence is body size ${ }^{12 \cdot 13}$. Therefore, the interpretation of blood pressure for individual adolescent requires some adjustment by age and body size.

The age- and height- based reference tables of blood pressure, developed by the Task Force on Blood Pressure Control in Children ${ }^{14}$, are usually used by pediatricians. However, it has been shown that ethnic
or genetic factors play a significant role in the blood pressure levels of a given population ${ }^{15}$. Since few studies have been conducted on the blood pressure of children and adolescents in Iran, the present study was designed to determine blood pressure distribution in a group of Iranian adolescents.

## Materials and Methods

Study population:
Tehran Lipid and Glucose study (TLGS) is a longitudinal study in which the first phase is a crosssectional population study or a baseline examination survey ${ }^{5,16 \cdot 17}$. It has been designed to measure the prevalence of risk factors, including dyslipoprotenemia, hyperglycemia, obesity, smoking, and hypertension, for a representative sample of 15005 persons aged $\geq 3$ years of an Iranian urban population from district No. 13 of Tehran. Details for TLGS, its rationale and design have been published elsewhere ${ }^{16}$. In this article, we dealt with distribution of blood pressure in 2560 TLGS subjects between 10-17 years of age.

[^0]
## Blood Pressure and Height Measurement:

Participants were initially been told to rest for 15 minutes. Then a trained and qualified physician measured blood pressure twice during physical examinations in a seated position after one initial measurement for determining peak inflation level using a standard mercury sphygmomanometer calibrated by the Iranian Institute of Standards and Industrial Researches. On the basis of the circumference of the participant's arm, an appropriate cuff (pediatric or regular) was chosen. The recordings were taken as recommended by the American Heart Association ${ }^{18}$. Height was measured in the upright position, without shoes, according to the standard protocol. All the procedures were performed at the research unit of the Tehran Lipid and Glucose (TLGS Unit) in the field center between 8 am and 2 pm .

## Statistical Methods:

Subjects aged 10-17 years were initially selected and categorized into four age groups in each gender. The means, standard deviations, and percentiles of systolic and diastolic blood pressures by sex and age with respect to the height group were calculated by means of SPSS 9.05 statistical software package (SPSS Inc., Chicago, IL, US). Height was categorized into four groups: <25th, 25 th- 49 th, 50 th -74 th, and $\geq 75$ th percentiles for each gender of different age strata. Measured heights were allocated accordingly. Pearson's and Spearman's correlation coefficients between SBP or DBP and the other variables were also calculated. This study was approved by appropriate Research Ethics Committee and informed consent was obtained from all participants or their parents.

## Results

Altogether, 2560 individuals ( 1247 boys and 1313 girls) participated in the survey. Table I summarizes the characteristics of the studied population. The relationships between SBP or DBP and age, height, weight or body mass index (BMI) were assessed in boys and girls, separately. Pearson's and Spearman's correlation coefficients between SBP or DBP and the other variables are shown in Table II. Significant associations were found between blood pressure and all other variables. SBP had a stronger association with each variable than DBP. The strongest relationships were found between blood pressures and weight. The associations between SBP and age, height, weight and BMI were more prominent in boys than in girls, while DBP showed stronger associations in girls than boys. Percentiles of height in different sex and age groups are shown in Table III. Clear differences were observed between results from this study and that conducted in the USA. Boys and especially girls in the current study were shorter than their USA counterparts and these differences were more prominent in late adolescence. Tables IV and V present 90 th and 95 th percentiles of SBP and DBP in different age and height groups in boys and girls, respectively. In comparison with the 90 th and 95 th percentiles of SBP in similar age and height groups in the Task Force study, our boys and girls generally showed lower SBP percentiles, especially in late adolescence. In contrast, the DBP percentiles of our boys and girls were prominently higher than their counterparts in the Task Force study, especially in early adolescence.

Table I: Characteristics of the studied adolescent population, Tehran Lipid and Glucose Study

| Characteristic | Boys ( $\mathrm{n}=1247$ ) | Girls ( $\mathrm{n}=1313$ ) | $\boldsymbol{t}$ | P-value |
| :--- | :---: | :---: | :---: | :---: |
| Age (years) | $13.61 \pm 2.23$ | $13.64 \pm 2.23$ | -0.313 | 0.755 |
| Height $(\mathrm{cm})$ | $156.61 \pm 14.78$ | $153.37 \pm 9.73$ | 4.725 | $<0.001$ |
| Weight $(\mathrm{kg})$ | $49.16 \pm 16.68$ | $47.33 \pm 12.87$ | -1.171 | 0.002 |
| BMI $(\mathrm{kg} / \mathrm{m} 2)$ | $19.54 \pm 4.32$ | $19.85 \pm 4.11$ | 6.542 | 0.057 |
| SBP $(\mathrm{mmHg})$ | $105.71 \pm 12.00$ | $103.54 \pm 11.28$ | 3.101 | $<0.001$ |
| DBP (mmHg) | $70.48 \pm 9.19$ | $70.91 \pm 9.39$ | -1.902 | 0.242 |

Table II: Correlation between SBP or DBP and age, height, weight or BMI in adolescents, Tehran Lipid and Glucose Study

|  |  | Boys ( $\mathbf{n}=\mathbf{1 2 4 7 )}$ |  |  |  |  | Girls (n=1313) |  |  |  |
| :--- | :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Age | Height | Weight | BMI | Age | Height | Weight | BMI |  |
| SBP | Pearson's | 0.261 | 0.289 | 0.449 | 0.430 | 0.189 | 0.218 | 0.390 | 0.383 |  |
|  | Spearman's | 0.255 | 0.291 | 0.405 | 0.378 | 0.191 | 0.224 | 0.376 | 0.369 |  |
| DBP | Pearson's | 0.101 | 0.130 | 0.221 | 0.218 | 0.166 | 0.177 | 0.301 | 0.293 |  |
|  | Spearman's | 0.101 | 0.138 | 0.195 | 0.171 | 0.166 | 0.191 | 0.294 | 0.280 |  |

All correlations are significant at the 0.001 level (2-tailed)

Table III: Height distribution by age and sex, Tehran Lipid and Glucose Study

|  |  |  | Percentile of height (cm) |  |  |  |  |

## Discussion

The 90 th and 95 th percentiles of systolic and diastolic blood pressure were obtained for different sex, age and height subgroups of adolescents. Comparison of these percentiles with current guidelines indicates a prominent discrepancy. In spite of some controversies regarding the importance of high blood pressure levels in adolescence, most authorities agree that detection of adolescents with significant hypertension through annual examinations and their careful monitoring has some indisputable benefits ${ }^{19-21}$. The most widely used definition of adolescent hypertension is based on epidemiological studies. Normal blood pressure is defined as SBP and DBP less than the 90th percentile for age, sex and height. High normal blood pressure is defined as SBP or DBP between the 90 th and 95 th percentiles and significant hypertension SBP or DBP equal to or above the 95 th percentile for age, sex and height.

Because of the lack of comprehensive and reliable data concerning blood pressure of adolescents outside North America, most countries use the reference tables developed by the Task Force study for everyday practice. Data in the Update on the Second Task Force report in 1996, 14 had been obtained from 10 different studies performed in the US and Canada between 1976 and 1991. These surveys involved more than 60,000 white, black and Mexican-American ( $56 \%$ white) children and adolescents between 1 and 18 years of age ${ }^{14}$. However, several epidemiological surveys have reported deviations from the Task Force guidelines regarding adolescent hypertension ${ }^{22}$. Our study also demonstrated prominent deviations from Task Force guidelines. These findings make it necessary to consider the ethnical and geographical variability of adolescent blood pressure in everyday practice and to prepare reference tables according to regional population-based surveys. Our study may serve to prepare such guidelines for the Eastern Mediterranean and South Asian regions.

The 90th and 95 th percentiles of SBP in our study were generally lower than corresponding values seen in the Task Force study. This discrepancy is more prominent in late adolescence. This can be explained by the shorter height of our adolescents especially in late adolescence and the strong positive association
between SBP and height. In addition, we used the mean of two blood pressure measurements in our study while in the Task Force study, only the first reading had been used, a factor that might also has contributed to the observed discrepancy. However, our 90 th and 95 th percentiles of DBP were greater than those of the Task Force study. This discrepancy is contradictory to the predicted discrepancy according to height. It may be regarded as the effect of diverse genetic and environmental factors. However, it should be remembered that a weaker association exists between DBP (rather than SBP) and height. This association, however, may explain the finding that this difference decreases with age, while the height differences become more significant.

The SBP of boys is significantly higher than girls. This is in agreement with present literature ${ }^{14}$. However, no significant difference was observed between boys and girls regarding DBP. Both DBP and SBP, the latter in particular, displayed strong correlations with age, height, weight and BMI. The stronger association between SBP (rather than DBP) and these variables have been reported earlier. The strongest relationship was found between SBP or DBP and weight rather than age, height or BMI. This is also in agreement with previous reports ${ }^{22}$, indicating possibly that considering weight rather than height may be better if used for the assessment of blood pressure in adolescents.

## Conclusion

In conclusion, considering the geographical variability of systolic and diastolic blood pressures observed, it is advisable for clinicians to be cautious in the application of existing guidelines being used to assess the blood pressure of adolescents and to emphasize the need to establish new guidelines on the basis of regional population-based surveys.

## Acknowledgements

This research project has been supported by grant No. 121 NRCI Research Project and with the support of National Research Council of Islamic Republic of Iran. We express appreciation to the participants of district13, Tehran, for their enthusiastic support in this study.
